Heat Sensitive Recording Material

The present invention relates to heat sensitive recording materials. It more particularly relates to such recording material in the form of a supporting substrate, for example, a paper sheet, synthetic paper sheet or plastic resin film coated with colour-forming systems comprising a colourless or pale coloured electron donative compound (colour forming compound) and an organic electron acceptor (developer).

Heat sensitive recording has conventionally been used as a system for recording transferred information through the mediation of heat, by utilising a colour reaction between a colour forming compound and a developer.

The properties which are most desirable in a colour forming material, in addition to the effective development of colour, are thermal response, background whiteness and image stability, especially light fastness of the developed colour, heat and moisture fastness of the developed colour, oil fastness of the developed colour, plasticiser resistance of the developed colour and water fastness of the developed colour.

A need exists to improve the above properties and to improve the archival capabilities of such recording materials. It is an object of the present invention to provide heat sensitive recording materials with improved properties, especially to provide an increase in image stability whilst improving the background whiteness of the paper before imaging and the background whiteness of the undeveloped portion after imaging.

The present invention is directed to a heat sensitive recording material, comprising

- a) at least one colour forming compound, and
- b) at least one developer of the formula

It is also possible to use solid solutions comprising at least two colour forming compounds.

A monophase (or single-phase or guest-host) solid solution possesses a crystal lattice which is identical with the crystal lattice of one of its components. One component is embedded as the 'guest' in the crystal lattice of the other component, which acts as the 'host'. The X-ray diffraction pattern of such a monophase solid solution is substantially identical to that of one of the components, called the 'host'. Within certain limits, different proportions of the components produce almost identical results.

In the literature, the definitions by the various authors, such as, G.H. Van't Hoff, A.I. Kitaigorodsky and A. Whitacker for solid solutions and mixed crystals are often contradictory, (cf, e.g. 'Analytical Chemistry of Synthetic Dyes', Chapter 10/page 269, Editor K. Venkataraman, J. Wiley, New York, 1977).

The term 'monophase solid solution' or 'multiphase solid solution' or mixed crystal', as defined herein, therefore, should be taken from the following definitions, which have been adapted to the current improved state of knowledge of such systems:

A monophase (or single-phase or guest-host) solid solution possesses a crystal lattice which is identical with the crystal lattice of one of its components. One component is embedded as the 'guest' in the crystal lattice of the other component, which acts as the 'host'. The X-ray diffraction pattern of such a monophase solid solution is substantially identical to that of one of the components, called the 'host'. Within certain limits, different proportions of the components produce almost identical results.

A multiphase solid solution possesses no precise, uniform crystal lattice. It differs from a physical mixture of its components in that the crystal lattice of at least one of its components is partially or completely altered. In comparison to a physical mixture of the components, which gives an X-ray diffraction diagram that is additive of the diagrams seen for the individual components. The signals in the X-ray diffraction diagram of a multiphase solid solution are broadened, shifted or altered in intensity. In general, different proportions of the components produce different results.

A mixed crystal (or solid compound type) solid solution possesses a precise composition and a uniform crystal lattice, which is different from the crystal lattices of all its components. If

different proportions of the components lead, within certain limits, to the same result, then a solid solution is present in which the mixed crystal acts as a host.

For the avoidance of doubt it may also be pointed out that, inter alia, there may also be amorphous structures and mixed aggregates consisting of different particles of different physical type, such as, for example, an aggregate of different components each in pure crystal modification. Such amorphous structures and mixed aggregates cannot be equated with either solid solutions or mixed crystals, and possess different fundamental properties.

As hereinbefore detailed, the monophase solid solutions comprise a plurality of colour compounds. Suitable colour forming materials which may be included in the solid solutions are those given above.

The monophase solid solutions can be used singly or as a mixture with other colour forming compounds such as triphenylmethanes, lactones, fluorans, benzoxazines and spiropyrans; or they may also be used together with further black colour forming compounds. Examples of such other colour forming compounds are given hereinbefore.

The monophase solid solutions can be prepared by a variety of methods. One such method is the recrystallisation method wherein a physical mixture of the desired components is dissolved, with or without heating, in a suitable solvent or solvent mixture. Suitable solvents include but are not limited to toluene, benzene, xylene, dichlorobenzene, chlorobenzene, 1,2-dichloroethane, methanol, ethanol, iso-propanol, n-butanol, acetonitrile, dimethylformamide or mixtures of these solvents with each other and with water. The monophase solid solution is then isolated by crystallisation from the solvent or solvent mixture. This can be brought about by cooling, standing, addition of a further solvent to promote crystallisation or concentration by standard means such as distillation, steam distillation and vacuum distillation. When the monophase solid solution is isolated by concentration it may be advantageous to do so in the presence of a small amount of base, to improve the visual aspect of the isolated product.

Alternatively, monophase solid solutions can be prepared from mixtures of the appropriate starting materials. The technique can be used to produce mixtures of two or more fluorans or phthalides. For example, mixtures of two fluorans are produced by replacing a single starting material with two analogous materials to the same total molar concentration in the reaction. In the case of fluorans, these starting materials are derivatives of amino phenols, phthalic anhydrides, keto acids and diphenylamines.

In addition, the heat sensitive recording material can contain a previously known developer, unless the colour forming performance of the resultant heat sensitive material is disturbed thereby. Such developers are exemplified by but not limited to; 4,4'-isopropylidene

#### Synthesis Example 1

Preparation of N-(p-toluenesulphonyl)-N'-(3-n-butylaminosulphonylphenyl) urea.

- 21 -

To a stirred solution of 4.6g aminobutylbenzenesulphonamide in 10g dimethylformamide at room temperature was added 4.14g toluenesulphonylisocyanate. After three hours at room temperature 0.65g toluenesulphonylisocyanate was added and stirring continued for one hour. To the reaction mixture was added water and methanol to precipitate the product as a white solid which was isolated by filtration and washed with methanol. After drying in vacuo at 80°C the product was obtained in 8.1g yield, melting point 153-153.3°C.

### Synthesis Example 2

Preparation of N-(p-toluenesulphonyl)-N'-(4-trimethylacetophenyl) urea.

A mixture of 22.3g 4-nitrophenyltrimethylacetate and 300g of isopropanol was charged to a Buchi catalytic hydrogenator with 2g 5%Pd-C. The mixture was then hydrogenated at 60°C and 10bar until hydrogen uptake ceased. The reaction mixture was cooled, filtered and the solvent removed to yield 18.7g of 4-aminophenyltrimethylacetate as a white solid, melting point 56.2-56.5°C.

The 4-aminophenyltrimethylacetate 15.4g, was then converted to the product using the method described in Example 1 to give 27g of a white solid which was isolated by filtration and washed with isopropanol, melting point 177.8-178.3°C.

### Synthesis Example 3

To a stirred solution of 5.65g m-aminophenol in 45ml acetonitrile was added dropwise 9.5g benzenesulphonylisocyanate such that the temperature was maintained at <40°C. The mixture was stirred for one hour at room temperature and allowed to stand overnight. To the reaction was then added 25ml water and 5.35g 47% caustic soda and the reaction was heated to 55-60°C. To this was added, over two hours, 9.93g p-toluenesulphonylchloride with simultaneous addition of 47% caustic soda so as to maintain the pH between 10 and 11. After two hours at 60°C the reaction mass was neutralised with hydrochloric acid to produce a thick white precipitate of the desired product. This was isolated by filtration and washed with water to give after drying 21.1g of product, melting point 162-170°C.

### Synthesis Example 4

Additionally, the recording paper obtained shows a high dynamic sensitivity.

#### DESCRIPTION OF TEST METHODS:

##### Background Whiteness Before and After Ageing:

This test assesses the effects of heat and moisture on unprinted thermal paper.

The whiteness of unprinted paper is measured using a Macbeth 1200 series Densitometer, before and after ageing for one hour at 60°C and 50% R.H.

##### Dynamic Sensitivity at Various Pulse Widths:

This test assesses the sensitivity and intensity of the image produced on thermal paper.

Ten individual print areas are printed with increased amounts of energy using an Atlantek thermal response tester model 200. The optical density of each image is measured using a Macbeth 1200 series Densitometer.

Lightfastness Tests (120 Hours Exposure):

This test assesses the stability of the thermal paper, including the image, after exposure to sunlight.

An image is produced using an Atlantek thermal response tester model 200. The image including background is placed at a distance of 8cm below 40W fluorescent tubes emitting artificial sunlight (approximately 1200 Lux) for 120 hours. The optical density of the image and background whiteness of the paper are measured before and after exposure with a Macbeth 1200 series Densitometer.

Cottonseed Oil Resistance of Image:

This test assesses the stability of the image when exposed to cottonseed oil.

An image is produced using an Atlantek thermal response tester model 200. Cottonseed oil is then Gravure printed onto the image which is then stored at 40°C for 24 hours. The optical density of the image is measured using a Macbeth 1200 series Densitometer before and after exposure.

Plasticiser Resistance of Image and Background:

This test assesses the stability of the image and background when exposed to PVC containing 20-25% phthalate ester-type plasticiser.

An image is produced using an Atlantek thermal response tester model 200. The image is put into contact with the PVC under 107g cm<sup>-2</sup> pressure for 24 hours at 50°C. The optical density of the image and background are measured using a Macbeth 1200 series Densitometer before and after exposure.

**Waterfastness of Image:**

This test assesses the stability of the image after immersion in water.

An image is produced using an Atlantek thermal response tester model 200. The image is immersed in de-ionised water at room temperature for 24 hours. The optical density of the image is measured using a Macbeth 1200 series Densitometer before and after immersion.

**Heat and Moisture Resistance of Image:**

This test assesses the effects of heat and moisture on the image.

An image is produced using an Atlantek thermal response tester model 200. The image is aged at 60°C at 70% R.H. for 24 hours. The optical density of the image is measured using a Macbeth 1200 series Densitometer before and after exposure.

**Heat Resistance of Image and Background at 80°C:**

This test assesses the effect of heat on both the image and background of thermal paper.

An image is produced using an Atlantek thermal response tester model 200. The image is aged at 80°C for 24 hours. The optical density of the image and background are measured using a Macbeth 1200 series Densitometer before and after exposure.

**Static Sensitivity and Background Storage Stability**

This test determines the thermal sensitivity of thermal paper.

Thermal paper is exposed to a range of temperatures for a fixed period of 1 second. Twelve separately heated blocks at 50°, 60°, 70°, 75°, 80°, 85°, 90°, 95°, 100°, 110°, 120° and 150°C are applied to the paper to produce an image. The optical density of each image is measured using a Macbeth 1200 series Densitometer.

From the static sensitivity, the temperature at which a density of 0.2 occurs is calculated. This temperature gives an indication of the background storage stability of the paper.

#### Examples 2 to 48

The following Table 2 shows the colour former/developer/sensitiser combinations that were used in each example. The heat sensitive recording material was prepared by the method described in example 1. In all cases, the heat sensitive recording paper thus obtained demonstrates excellent background whiteness of paper after application of the coating liquid and in storage stability, i.e. resistance to light, heat and moisture, of uncoloured portion of the coated paper and excellent resistance of the image to cottonseed oil, plasticiser, heat, heat and moisture, water.

**Example 49**

Preparation of heat sensitive coating formulations containing N-(p-toluenesulphonyl)-N'-(3-p-toluenesulphonyloxyphenyl) urea and a stabiliser.

Dispersions A to D were prepared by grinding the compositions shown below in an attritor until an average particle size of 1-1.5 $\mu$  was attained.

**Dispersion A (Colour Former)**

3-dibutylamino-6-methyl-7-anilino-fluoran	3.01 parts
Polyvinyl alcohol (10% aqueous solution)	10.50 parts
Water	6.49 parts

**Dispersion B (Colour Developer)**

N-(p-toluenesulphonyl)-N'-(3-p-toluenesulphonyloxyphenyl) urea	7.5 parts
Polyvinyl alcohol (10% aqueous solution)	7.5 parts
Water	22.5 parts

**Dispersion C (Sensitiser)**

parabenzylbiphenyl	10.0 parts

1,1,3-tris(3'-cyclohexyl-4'-hydroxy-6'-methylphenyl)butane	7.5 parts
Polyvinyl alcohol (10% aqueous solution)	7.5 parts
Water	22.5 parts

A thermal coating mixture was then prepared by combining together the following components:

	parts by weight
Dispersion A	6.6

- 35 -

Dispersion B	10.0
Dispersion C	6.0
Dispersion D	2.5
Calcium Carbonate (25% aqueous dispersion)	12.0
Zinc stearate (33% aqueous dispersion)	0.9
Polyvinyl alcohol (10% aqueous solution)	4.5
